Grout Injection in to Adjacent Strata for Water Control (Grout Curtain)

Directionally drilled boreholes may be placed in to underlying/overlying strata or steered to particular targets for injection of cementitious or chemical grout. Single boreholes or multi-lateral boreholes may be developed to maximize coverage area and formation of a grout curtain to slow or stop inflows of water in to mine workings. High pressure grout pumps are utilized to inject grout in to water bearing formations or fracture zones via a sealed standpipe or through down hole packers.
